AB A glassy carbon (GC) electrode modified by paste containing multi-walled carbon nanotubes (MWNTs) and room-temperature ionic liq. of 1-butyl-3-methylimidazoliumhexafluorophosphate (BMIMPF6) was prepared, and the electrochem. behaviors of epinephrine (EP) at this electrode were studied. It was found that EP could generate a sensitive anodic peak in pH 7 phosphate buffer and the paste made the peak move about 40 mV in neg. direction, compared with at MWNTs

modified GC electrode. Under the optimum conditions, the anodic peak current of EP was linear to its concentration over the range of 5.0×10^{-7} .apprx. 2.0×10^{-5} mol · L⁻¹ by cyclic voltammetry, the correlation coefficient was 0.998. The detection limit was estimated to be 1.0×10^{-7} mol · L⁻¹. The method was applied to the determination of EP in injection samples.

AB Acidic treated multiwalled carbon nanotubes (AMWNTs) were ground with water-miscible room temperature ionic liqs., 1-butyl-3-methylimidazolium tetrafluoroborate ([bmim]BF₄), and resulted in AMWNTs-[bmim]BF₄ composite. Its elec.-ionic conductivity and optical properties were compared with the other two types of carbon materials-[bmim]BF₄ composites: pyrolytic graphite powder (PGP), pristine multiwalled carbon nanotubes (PMWNTs), through the ac impedance technol. and Raman spectroscopy. The impedance data show that AMWNTs-[bmim]BF₄ composite exhibits the highest conductivity Raman spectra study

exhibits that the [bmim]BF₄ can form gel with PMWNTs and AMWNTs but only form a viscous liquid with PGP. AMWNTs-[bmim]BF₄ gel modified GC electrode was applied in direct electrochem. of heme proteins (Hb and HRP) and its catalysis to the reduction of H₂O₂ was investigated.

AB The C nanotubes (CNTs) based microelectrode (ME) by modifying CNTs-room

temperature ionic liq. (IL) gel at C fiber microelectrode (CFME) is easily prepared, which exhibits the typical cyclic voltammogram of ME with sigmoid shape and possesses good stability, high conductivity and enlarged current response and tunable dimension. The direct electron transfer of glucose oxidase was greatly promoted showing reversible electrochem. behavior even at high scan rate. The CNTs based ME also exhibits effectively electrocatalytic oxidized ability to biomols., e.g. dopamine (DA), ascorbic acid (AA) and dihydronicotinamide adenine dinucleotide. The obvious separation of oxidized peak potential for DA and AA makes it possible to selectively determine DA in presence of AA. These phenomena show that the CNTs based ME has promising potential to detect various species in vivo and in vitro.

AB A review. This article focuses on our recent studies on the development of soft materials consisting of graphitic nanostructures. We found that single-walled carbon nanotubes, when suspended in imidazolium ion-based ionic liqs. and ground in an agate mortar, form phys. gels (bucky gels), where entangled nanotube bundles are exfoliated to give highly dispersed, much finer bundles. The use of polymerizable ionic liqs. as the gelling media leads to the formation of highly electroconductive polymer/nanotube composites, which show a dramatic enhancement in mech. properties. Bucky gels allow the fabrication of the first printable actuator that operates for a long time in air at low applied voltages. We also succeeded in the development of a new family of nanotubular graphite through self-assembly of amphiphilic hexabenzocoronene derivs. The nanotube consists of a graphitic wall formed from a great number of π -stacked hexabenzocoronene units, which provide a charge carrier transport pathway. Suitable chemical modifications of the amphiphile resulted in the formation of nanotubes with various interesting properties. Details of the design, properties, and scope of such π -electronic soft nanomaterials are described herein.

DOCUMENT TYPE: Journal
LANGUAGE: English

AB Electrochem. properties of a new nanomaterial ferrocene (Fc) peapod, Fc-filled single-walled C nanotubes (Fc@SWNTs), were studied in an aqueous solution in detail by preparing different kinds of Fc@SWNTs-modified glassy C electrodes (Fc@SWNTs/GCE and Fc@SWNTs-gel/GCE). One pair of surface-confined redox waves corresponding to the couple of Fc/Fc⁺ is obtained, which indicates that Fc encapsulated inside SWNTs retains electrochem. activity. The Fc@SWNTs-gel/GCE shows better electrochem. reversibility due to the existence of room temperature ionic liq. (RTIL). Also, it shows excellent mediation of H₂O₂ based on Fc/Fc⁺ used as electron-transfer mediators for oxidation of H₂O₂ to O₂ and reduction to H₂O, suggesting specific properties of Fc@SWNTs due to a combination of Fc and SWNTs. The interaction between Fc and SWNTs is also characterized by UV-visible-NIR spectrometry and Raman spectrometry. A Fc@SWNTs-based sensor for H₂O₂ with a determination limit of 5 μM is fabricated, and it shows good stability and reproducibility. This work not only demonstrates that the Fc peapod is a new kind of functional nanomaterial but also appears promising in constructing novel chemical and biosensors and fuel cells.

CODEN: ELANEU; ISSN: 1040-0397

PUBLISHER: Wiley-VCH Verlag GmbH & Co. KGaA

DOCUMENT TYPE: Journal

LANGUAGE: English

AB The voltammetric behavior of uric acid (UA) was studied at a multiwalled carbon nanotube-ionic liq. (i.e., 1-butyl-3-methylimidazolium hexafluorophosphate, BMIMPF₆) paste coated glassy carbon electrode (MWNTs-BMIMPF₆/GC). UA can effectively accumulate at this electrode and cause a sensitive anodic peak at .apprx.0.49 V (vs. SCE) in pH 4.0 phosphate buffer solns. Exptl. parameters influencing the response of the electrode, such as solution pH and accumulation time, are optimized for uric acid determination Under the optimum conditions, the anodic peak current is linear to UA concentration in the range

of

1.0 + 10⁻⁸ M to 1.0 + 10⁻⁶ M and 2.0 + 10⁻⁶ M to 2.0

+ 10⁻⁵ M. The detection limit is 5.0 + 10⁻⁹ M for 180 s

accumulation on open circuit. The electrode can be regenerated by successively cycling in a blank solution for .apprx.3 min and exhibits good reproducibility. A 1.0 + 10⁻⁶ M UA solution is measured for eight times using the same electrode regenerated after every determination, and the relative standard deviation of the peak current is 3.2%. As for different electrodes fabricated by the same way the relative standard deviation (i.e., the electrode to electrode deviation) is 4.2%(n = 9). This method was applied to the determination of UA in human urine samples, and the recoveries

are

99-100.6%. Comparison is made between MWNTs-BMIMPF₆/GC and MWNTs/GC. The MWNTs-BMIMPF₆/GC exhibits higher sensitivity, selectivity and ratio of peak current to background current.

AB A novel electrochem. biosensor for the detection of uric acid and adenine was prepared based on a gel containing multi-walled carbon nanotubes and room-temperature ionic liq. of 1-octyl-3-methylimidazolium hexafluorophosphate. The electrochem. of uric acid and adenine was studied in this gel modified electrode. There was a significant two-way electrocatalytic activity upon both oxidation and reduction of uric acid. Similar to a bare glassy carbon electrode, uric acid undergoes a $2e, 2H^+$ oxidation in phosphate buffer in the modified electrode. A diimine, the oxidation product of uric acid, was found to be an unstable intermediate, which was converted by a follow-up hydration reaction to an imine alc., with the reaction rate constant of $8.5 \pm 0.3 \text{ M}^{-1} \cdot \text{s}^{-1}$ according to Nicholson's theory. Under optimum conditions, linear calibration graphs were obtained over the concentration range of $1.0 \times 10^{-7} \text{ M}$ to $1.0 \times 10^{-5} \text{ M}$ (uric acid) and $1.0 \times 10^{-5} \text{ M}$ to $6.0 \times 10^{-4} \text{ M}$ (adenine). Based on the signal-to-noise ratio of 3, the detection limits of the current technique was found to be as low as $9.0 \times 10^{-8} \text{ M}$ (uric acid) and $2.0 \times 10^{-6} \text{ M}$ (adenine), resp. This novel biosensor was successfully applied for the assay of uric acid in human urine. Because of its good stability and long-term durability, such a gel modified electrode can provide a simple and easy approach for sensitive detection of uric acid and adenine.

AB Ionic liq., n-octylpyridinium hexafluorophosphate (OPFP) was used to fabricate a new carbon composite electrode with very attractive electrochem. behavior. This type of carbon electrode was constructed using graphite mixed with OPFP as the binder. The electrode has combined advantages of edge plane characteristics of carbon nanotubes and edge plane pyrolytic graphite electrodes together with the low cost of carbon paste electrodes and robustness of metallic electrodes. It provides a remarkable increase in the rate of

electron transfer of different organic and inorg. electroactive compds. and offers a marked decrease in the overvoltage for biomols. such as NADH, dopamine, and ascorbic acid. It also circumvents NADH surface fouling effects as well as furnishing higher c.d. for a wide range of compds. tested. Depending on the choice of the electrolyte, the electrode can have the ion-exchange property and adsorptive characteristics of clay-modified electrodes. The proposed electrode thus allows sensitive, low-potential, simple, low-cost, and stable electrochem. sensing of biomols. and other electroactive compds. SEM images indicate significant improvement in the microstructure of the proposed electrode compared to carbon paste electrodes. Such abilities promote new opportunities for a wide range of electrochem. and biosensing applications.

AB Single walled carbon nanotubes (SWCNT) and room temperature ionic liq. (RTIL) were used to make a gel microelectrode for studies of the oxidation of nitric oxide (NO). The Faraday response of the gel microelectrode was contributed from 2 components: an outside-surface microdisk and a thin-layer cell formed by inner porous electrode materials, and enhanced by the thin-layer effect. An EC mechanism, electrochem. NO oxidation followed by a chemical oxidation, was proposed. The gel microelectrode with a Nafion coating eliminated interferences from nitrite and some biomols., improved stability, and had a linear response range from 100 nM to 100 μ M.

AB We have reported that an amphiphilic hexa-peri-hexabenzocoronene (HBC) self-assembles to form graphitic nanotubes, which turn elec. conductive upon oxidation. Spray deposition allows spontaneous alignment of HBC on a 2D substrate surface. Recently, we also found that a chiral HBC amphiphile forms highly qualified nanotubes that can be fished by using a glass hook

to give a macroscopic fiber consisting of one-dimensionally aligned nanotubes, which exhibit anisotropic elec. conduction. This is due to a strong interfacial interaction among the nanotubes with a very long aspect ratio. We have also reported that bundled single-walled carbon nanotubes (SWNTs) are exfoliated, upon being ground in ionic liqs. (ILs), to afford bucky gels, which can be converted into bucky plastics when ionic liqs. carry a polymerizable group. Because of a strong interfacial interaction of highly dispersed SWNTs with IL polymer matrixes and their crosslinked network structure, bucky plastics are highly reinforced mech. and elec. conductive.

AB Single-walled carbon nanotubes (SWNTs) formed
gels after being ground with a room-temperature ionic
liq. (RTIL). The gels were used as electrodes of elec.
double-layer capacitors (EDLCs), and the RTIL was used as the electrolyte.
The performance of the EDLCs was examined by charge-discharge expts. and was
compared with that of the EDLCs using activated carbon electrodes and the
RTIL electrolytes. The gels functioned as the electrodes over a
wide composition range from 0.02 to 0.12 of SWNT/RTIL (wt/wt), and the retained
capacitance increased with increasing the SWNT comps. The EDLCs with the
SWNTs showed higher capacitance than that with the activated carbons in
terms of the capacitance per unit surface area, though the gravimetric
capacitance was lower. The gel electrodes can be fabricated as
thick as 3 mm without a severe ohmic-drop problem, which may contribute to
a simple cell structure. The changes in the performance of the
SWNT-EDLCs, with or without the gelation, were apparent, and the gelation
greatly contributed to the high performance. This is due to the formation
of continuous SWNT and RTIL paths at the mol. level by the gelation.

AB A gel-like paste was prepared by mixing
1-n-butyl-3-methylimidazolium tetrafluoroborate, ([Bmim] BF₄) a room
temperature ionic liq. (RTIL) and single-walled
carbon nanotubes (SWNT) and the internal structure and
viscoelastic characteristics of the gels were studied. A
suspension of BmimBF₄ containing 1% SWNT was prepared by grinding in an agate
mortar, followed by centrifugation to obtain the paste. Rheol.
properties of a purified SWNT-BmimBF₄ gel were measured using a
rotational rheometer with parallel plate geometry, and compared with those
of non-purified SWNT-ionic liq. gel from
both steady shear and oscillatory shear mode tests. The gels
show high shear thinning, dynamic yield stress, and frequency independent
dynamics as evidence of strong interactions between the ionic
liq. and SWNT. The gel structure was followed by a
shear induced secondary structure in the high shear rate region.

AB Single Wall Carbon Nanotube (SWNT) gels were prepared by thermal treatment of nanotubes with ionic liqs. (ILs). These gels could be made with varying ratio of SWNTs and ILs, though a min. 0.5 wt % of SWNTs (to the total weight) was needed. Imidazolium based ionic liqs. with varied chain length and anions were employed, resulting in stable gel in each case. The products from each IL had different glass transition temperature compare to the ionic liq., as revealed by differential scanning calorimetry (DSC). Interestingly, solid ILs also resulted in stable gel on reaction with nanotubes, even in the absence of any solvent. The Transition electron microscopy (TEM) and SEM (SEM) showed that originally bundled pristine SWNTs are unbundled on treatment with ILs. The SWNT-IL nano-composites provide conducting material that are suitable for sensing devices.

AB Pristine single-walled carbon nanotubes form gels when ground with imidazolium ion-based room-temperature ionic liqs. In the gels, the heavily entangled nanotube bundles are exfoliated to give much finer bundles. Phase-transition and rheol. properties suggest that the gels are formed by phys. crosslinking of nanotube bundles mediated by local mol. ordering of ionic liqs., rather than entanglement of nanotubes. Single-walled carbon nanotube gels of ionic liqs., thus obtained, are thermally stable and do not shrivel even under reduced pressure, because of the non-volatility of the ionic liqs., but readily undergo gel-to-solid transition on absorbent materials. The use of a polymerizable ionic liq. as the gelling medium allowed for the fabrication of an electroconductive polymer/nanotube composite material, which showed significant enhancement in dynamic hardness due to strong connectivity at the polymer/nanotube interface.

AB The electrochem. of dopamine (DA) was studied by cyclic voltammetry at a
glassy carbon electrode modified by a gel containing multi-walled
carbon nanotubes (MWNTs) and room-temperature ionic
liq. of 1-octyl-3-methylimidazolium hexafluorophosphate (OMIMPF₆).
The thickness of gel on the surface of the electrode has to be
controlled carefully because the charging currents increase with the
modified layer being thicker. The anodic peaks of DA, ascorbic acid (AA)
and uric acid (UA) in their mixture can be well separated since the peak
potential of AA is shifted to more neg. values, while that of UA is
shifted to more pos. values due to the modified electrode. At pH 7.08 the
three peaks are separated ca. 0.20 and 0.15 V, resp.; hence DA can be
determined in
the presence of UA and more than 100 times excess of AA. Under optimum
conditions linear calibration graphs were obtained over the DA concentration
range 1.0×10^{-6} to 1.0×10^{-4} M. The detection limit of the
current technique was found to be 1.0×10^{-7} M based on the
signal-to-noise ratio of 3. The modified electrode has been successfully
applied for the assay of DA in human blood serum. This work provides a
simple and easy approach to selectively detect dopamine in the presence of
ascorbic acid and uric acid.

AB A novel glassy carbon electrode modified by a gel containing multi-walled carbon nanotubes (MWNTs) and ionic liq. of 1-butyl-3-methylimidazolium hexafluorophosphate (BMIPF6) is reported. The gel is formed by grinding of MWNTs and BMIPF6. Such gel is then coated on the surface of a glassy carbon electrode. The authors have employed SEM, Fourier transform IR spectrometry (FTIR) and cyclic voltammetry to characterize the modified electrode. The direct electron transfers of Hb and catalase on the modified electrode have been observed and studied in detail electrochem. Hb is verified to be adsorbed on the modified electrode with the retention of conformation, which has been proved by microscopic FTIR. The electrochem. response of the adsorbed Hb on the modified electrode is very stable, and shows repeated changes in the different pH solns. It also has shown electrocatalysis to the reduction of oxygen and trichloroacetic acid. Catalase adsorbed on the gel modified electrode still keep activity to hydrogen peroxide. This work provides a simple and easy approach to construct biosensors based on the carbon nanotubes and ionic liqs.

AB The material is a gel containing carbon nanotube (CNT) and ionic liq. and absorbs laser light to generate heat. The method involves (1) printing the material by screen printing, (2) jetting the material from a nozzle, or (3) irradiating laser to the material to remove substances excluding CNT to concentrate CNT. The material utilizes electrocond., heat radiation, mech. strength, etc., of CNT, and is suitable for conductive pattern formation inks, etc., and the gel state improves handling and processability of CNT.

AB Ionic liqs. are interesting compds. for broad applications in green chemical and electrochem. Recently, we have found that grinding of single-walled carbon nanotubes (SWNTs) in imidazolium ionic liqs. results in the formation of phys. gels (bucky gels), in which SWNT bundles are highly untangled. On the basis of this discovery, we have succeeded in fabricating novel polymer composite materials called bucky plastics, which are highly reinforced and electroconductive even at low contents of SWNTs. We have also succeeded in the fabrication of elec. devices based on bucky gels. Here we report results of a detailed study on properties of these unique soft materials and further application of this hybridization method to other carbon and inorg. nanomaterials.

AB In this study, an effect of addition of nanoparticles into a dye-sensitized solar cells (DSCs) ionic liq. electrolyte was explored. Carbon nanotubes, other carbon nanoparticles and titanium dioxide nanoparticles were dispersed individually into a 1-ethyl-3-methylimidazolium bis(trifluoromethylsulfonyl)imide (EMIm-TFSI) ionic liq. electrolyte by grinding. It was centrifuged to form an ionic nanocomposite gel electrolyte. The dispersion of nanoparticles resulted in a substantial increase in their viscosity. Their elec. conductivity increased as well. Notable effects were obtained in photocurrent d. and voltage measurements of the DSC assembled with them. Energy conversion efficiency of them was significantly improved and increased compared with a DSC using a bare ionic liq. electrolyte.

AB A composition in the form of a gel comprising C nanotube and an ionic liq.; and a method for preparing the composition which comprises applying a shearing force to C nanotube in the presence of the ionic liq., to subdivide the C nanotube, and optionally subjecting the resulting product to centrifugal separation are described. The composition in the form of a gel is excellent in formability and can be formed only by forming it into a predetd. shape by means of printing, coating, extrusion or injection in a fluidized state provided by applying a slight external force, followed by removing the ionic liq. with a solvent or an absorbing material. The composition allows the forming of a C nanotube with ease and without detriment to the characteristics thereof.

AB Gelation of imidazolium ion-based ionic liqs. takes place after mixing with single-walled carbon nanotubes. The imidazolium-based ionic liqs. studied include 1-Ethyl-3-methylimidazolium tetrafluoroborate (EMIBF₄), 1-n-Butyl-3-methylimidazolium tetrafluoroborate (BMIBF₄), 1-n-Butyl-3-methylimidazolium hexafluorophosphate (BMIPF₆), 1-Ethyl-3-methylimidazolium bis(triflyl)amide (EMITSFSI), 1-Butyl-3-methylimidazolium bistriflimide (BMITFSI), and 1-methyl-3-[4-[(1-oxo-2-propenyl)oxy]butyl]-imidazolium hexafluorophosphate (ABMIPF₆). TEM data showed that heavily entangled nanotube bundles become untangled into finer bundles upon gelation. DSC, x-ray diffraction, and rheol. studies indicate that the gels (bucky gels) are formed by phys. crosslinking of the nanotube bundles, mediated by local mol. ordering of the ionic liqs., rather than by entanglement of the nanotubes. The use of ionic liqs. as gelling media allowed for fabrication of nanotube composites that are mech. reinforced and elec. conductive. The

carbon nanotube-based soft materials of interest for use
as components of electronic devices.

AB When mixed with imidazolium ion-based room-temperature ionic liq., pristine single-walled carbon nanotubes formed gels after being ground. The heavily entangled nanotube bundles were untangle within the gel to form much finer bundles. Phase transition and rheol. properties suggest that the gels are formed by phys. crosslinking of the nanotube bundles, mediated by local mol. ordering of the ionic liqs. rather than by entanglement of the nanotubes. The gels were thermally stable and did not shrivel, even under reduced pressure resulting from the nonvolatility of the ionic liqs., but they would readily undergo a gel-to-solid transition on absorbent materials. The use of a polymerizable ionic liq. as the gelling medium allows for the fabrication of a highly electroconductive polymer/nanotube composite material, which showed a substantial enhancement in dynamic hardness.
